

Domino / shibboleth idp authentication integration flow

Notes:

idp and domino running on same server with same server name component of URL, possibly on different ports or possibly behind reverse proxy on same port

idp_key will be a spring webflow execution key of the general form "e<integer>s<integer>" but should be treated as opaque; it just needs to be passed back as is to idp callback along with auth_id

auth_id from domino could be an explicit parameter or could be a cookie; it just needs to be passed from the domino auth mechanism to the idp when authentication is successful, and then passed from the idp to domino to validate the auth and retrieve username/attributes associated with it
